

## Filling an array from the left:

```
int[] arr = new int[10];
```

At step  $i$ , we shove down a “sub-array” of length  $i$  to make room for the new value at position 0. Start shoving from the right, toward the left (steps 1,2,3 below).

writing down these  
“concrete steps” can help!

```
arr[3] = arr[2];  
arr[2] = arr[1];  
arr[1] = arr[0];
```

```
arr[0] = 7;
```

Note that we can distinguish:

- the end result of the filling (“up”, from low to hi, or “down”, from hi to low)
- the direction the loop indices  $[i]$  actually ran (again, up or down)
- the direction in which we filled (from left-to-right or right-to-left)

## For the lab:

- write a `StopWatch` class to use for timing (methods: `start`, `stop`, `read`, `clear?`, ...);
- write a “harness” main class (`TimeTests`) that compares several ways of filling arrays and array lists, with regard to timing;
- first: fill arrays and `ArrayLists` from the *left*, using `add(0, ...)` for the `ArrayLists` and using “shoving” for the arrays.
- next: fill arrays and `ArrayLists` from the *right*, with `add(...)` for the `ArrayLists` and plain filling for the arrays (no shoving needed);
- all structures should be filled with  $1-n$ , (verified at both ends), no matter the fill direction (*note: not  $0-(n-1)$ , but  $1-n$* );
- compute timings for size  $n$  among the whole powers of 10 between 3 and 6 (i.e., from one thousand to one million, inclusive);
- report the various timings in some nice, readable, columnar format (use `printf`): two structures, two directions, four sizes.
- Extra fun: append (join together)  $n$  copies of some string, using either the `String` class and `+`, or `StringBuilder`; compare timings for various (big) sizes  $n$ .
